“Foundations of Data Science”

Lecture 15/16: Streaming algorithms

Slides at <http://grigory.us/data-science-class.html>

Grigory Yaroslavtsev

<http://grigory.us>

Recap

- (Markov) For every $c > 0$ (and non-negative X):

$$\Pr[X \geq c \mathbb{E}[X]] \leq \frac{1}{c}$$

- (Chebyshev) For every $c > 0$:

$$\Pr[|X - \mathbb{E}[X]| \geq c \mathbb{E}[X]] \leq \frac{\text{Var}[X]}{(c \mathbb{E}[X])^2}$$

- (Chernoff) Let $X_1 \dots X_t$ be independent and identically distributed r.v.s with range $[0, c]$ and expectation μ . Then if $X = \frac{1}{t} \sum_i X_i$ and $1 > \delta > 0$,

$$\Pr[|X - \mu| \geq \delta \mu] \leq 2 \exp\left(-\frac{t \mu \delta^2}{3c}\right)$$

Topics in streaming algorithms

- Approximate counting (Morris's alg.)
- Approximate Median
- Alon-Mathias-Szegedy Sampling
- Frequency Moments
- Distinct Elements
- Count-Min

Morris's Algorithm

- **(Hard puzzle, “Count the number of items”)**
 - What is the total number of elements in the stream up to error $\pm \epsilon n$?
 - You have $O(\log \log n / \epsilon^2)$ space and can be completely wrong with some small probability

Morris's Algorithm: Alpha-version

Maintains a counter X using $\log \log n$ bits

- Initialize X to 0
- When an item arrives, increase X by 1 with probability $\frac{1}{2^X}$
- When the stream is over, output $2^X - 1$

Claim: $\mathbb{E}[2^X] = n + 1$

Morris's Algorithm: Alpha-version

Maintains a counter X using $\log \log n$ bits

- Initialize X to 0, when an item arrives, increase X by 1 with probability $\frac{1}{2^X}$

Claim: $\mathbb{E}[2^X] = n + 1$

- Let the value after seeing n items be X_n

$$\begin{aligned}\mathbb{E}[2^{X_n}] &= \sum_{j=0}^{\infty} \Pr[X_{n-1} = j] \mathbb{E}[2^{X_n} | X_{n-1} = j] \\ &= \sum_{j=0}^{\infty} \Pr[X_{n-1} = j] \left(\frac{1}{2^j} 2^{j+1} + \left(1 - \frac{1}{2^j}\right) 2^j \right) \\ &= \sum_{j=0}^{\infty} \Pr[X_{n-1} = j] (2^j + 1) = 1 + \mathbb{E}[2^{X_{n-1}}]\end{aligned}$$

Morris's Algorithm: Alpha-version

Maintains a counter X using $\log \log n$ bits

- Initialize X to 0, when an item arrives, increase X by 1 with probability $\frac{1}{2^X}$

$$\text{Claim: } \mathbb{E}[2^{2X}] = \frac{3}{2}n^2 + \frac{3}{2}n + 1$$

$$\mathbb{E}[2^{2X_n}] = \sum_{j=0}^{\infty} \Pr[2^{X_{n-1}} = j] \mathbb{E}[2^{2X_n} | 2^{X_{n-1}} = j]$$

$$= \sum_{j=0}^{\infty} \Pr[2^{X_{n-1}} = j] \left(\frac{1}{j} 4j^2 + \left(1 - \frac{1}{j}\right) j^2 \right)$$

$$= \sum_{j=0}^{\infty} \Pr[2^{X_{n-1}} = j] (j^2 + 3j) = \mathbb{E}[2^{2X_{n-1}}] + 3\mathbb{E}[2^{X_{n-1}}]$$

$$= 3 \frac{(n-1)^2}{2} + 3(n-1)/2 + 1 + 3n$$

Morris's Algorithm: Alpha-version

Maintains a counter X using $\log \log n$ bits

- Initialize X to 0, when an item arrives, increase X by 1 with probability $\frac{1}{2^X}$
- $\mathbb{E}[2^X] = n + 1, \text{Var}[2^X] = O(n^2)$
- Is this good?

Morris's Algorithm: Beta-version

Maintains t counters X^1, \dots, X^t using $\log \log n$ bits for each

- Initialize X^i 's to 0, when an item arrives, increase each X^i by 1 independently with probability $\frac{1}{2^{X^i}}$
- Output $Z = \frac{1}{t} (\sum_{i=1}^t 2^{X^i} - 1)$
- $\mathbb{E}[2^{X^i}] = n + 1, \text{Var}[2^{X^i}] = O(n^2)$
- $\text{Var}[Z] = \text{Var} \left(\frac{1}{t} \sum_{j=1}^t 2^{X^j} - 1 \right) = O \left(\frac{n^2}{t} \right)$
- Claim: If $t \geq \frac{c}{\epsilon^2}$ then $\Pr[|Z - n| > \epsilon n] < 1/3$

Morris's Algorithm: Beta-version

Maintains t counters X^1, \dots, X^t using $\log \log n$ bits for each

- Output $Z = \frac{1}{t} (\sum_{i=1}^t 2^{X^i} - 1)$
- $Var[Z] = Var \left(\frac{1}{t} \sum_{j=1}^t 2^{X^j} - 1 \right) = O \left(\frac{n^2}{t} \right)$
- Claim: If $t \geq \frac{c}{\epsilon^2}$ then $\Pr[|Z - n| > \epsilon n] < 1/3$
 - $\Pr[|Z - n| > \epsilon n] < \frac{Var[Z]}{\epsilon^2 n^2} = O \left(\frac{n^2}{t} \right) \cdot \frac{1}{\epsilon^2 n^2}$
 - If $t \geq \frac{c}{\epsilon^2}$ we can make this at most $\frac{1}{3}$

Morris's Algorithm: Final

- What if I want the probability of error to be really small, i.e. $\Pr[|Z - n| > \epsilon n] \leq \delta$?
- Same Chebyshev-based analysis: $t = O\left(\frac{1}{\epsilon^2 \delta}\right)$
- Do these steps $m = O\left(\log \frac{1}{\delta}\right)$ times independently in parallel and output the median answer.
- Total space: $O\left(\frac{\log \log n \cdot \log \frac{1}{\delta}}{\epsilon^2}\right)$

Morris's Algorithm: Final

- Do these steps $m = O\left(\log \frac{1}{\delta}\right)$ times independently in parallel and output the median answer Z^m .

Maintains t counters X^1, \dots, X^t using $\log \log n$ bits for each

- Initialize X^i 's to 0, when an item arrives, increase each X^i by 1 independently with probability $\frac{1}{2^{X^i}}$
- Output $Z = \frac{1}{t} (\sum_{i=1}^t 2^{X^i} - 1)$

Morris's Algorithm: Final Analysis

Claim: $\Pr[|Z^m - n| > \epsilon n] \leq \delta$

- Let Y_i be an indicator r.v. for the event that $|Z_i - n| \leq \epsilon n$, where Z_i is the i -th trial.
- Let $Y = \sum_i Y_i$.
- $\Pr[|Z^m - n| > \epsilon n] \leq \Pr\left[Y \leq \frac{m}{2}\right] \leq$
 $\Pr\left[|Y - \mathbb{E}[Y]| \geq \frac{m}{6}\right] \leq \Pr\left[|Y - \mathbb{E}[Y]| \geq \frac{\mathbb{E}[Y]}{4}\right] \leq$
 $\exp\left(-c \frac{1}{4^2} \frac{2m}{3}\right) < \exp\left(-c \log \frac{1}{\delta}\right) < \delta$

Data Streams

- Stream: m elements from universe $[n] = \{1, 2, \dots, n\}$, e.g.

$$\langle x_1, x_2, \dots, x_m \rangle = \langle 5, 8, 1, 1, 1, 4, 3, 5, \dots, 10 \rangle$$

- Example:

Approximate Median

- $S = \{x_1, \dots, x_m\}$ (all distinct) and let
$$\text{rank}(y) = |\{x \in S : x \leq y\}|$$
- **Problem:** Find ϵ -approximate median, i.e. y such that
$$\frac{m}{2} - \epsilon m < \text{rank}(y) < \frac{m}{2} + \epsilon m$$
- **Exercise:** Can we approximate the value of the median with additive error $\pm \epsilon n$ in sublinear time?
- **Algorithm:** Return the median of a sample of size t taken from S (with replacement).

Approximate Median

- **Problem:** Find ϵ -approximate median, i.e. y such that
$$\frac{m}{2} - \epsilon m < \text{rank}(y) < \frac{m}{2} + \epsilon m$$
- **Algorithm:** Return the median of a sample of size t taken from S (with replacement).
- **Claim:** If $t = \frac{7}{\epsilon^2} \log \frac{2}{\delta}$ then this algorithm gives ϵ -median with probability $1 - \delta$

Approximate Median

- Partition S into 3 groups

$$\mathbf{S}_L = \left\{x \in S : \text{rank}(x) \leq \frac{m}{2} - \epsilon m\right\}$$

$$\mathbf{S}_M = \left\{x \in S : \frac{m}{2} - \epsilon m \leq \text{rank}(x) \leq \frac{m}{2} + \epsilon m\right\}$$

$$\mathbf{S}_U = \left\{x \in S : \text{rank}(x) \geq \frac{m}{2} + \epsilon m\right\}$$

- Key fact:** If less than $\frac{t}{2}$ elements from each of \mathbf{S}_L and \mathbf{S}_U are in sample then its median is in \mathbf{S}_M
- Let $X_i = 1$ if i -th sample is in \mathbf{S}_L and 0 otherwise.
- Let $X = \sum_i X_i$. By Chernoff, if $t > \frac{7}{\epsilon^2} \log \frac{2}{\delta}$

$$\Pr \left[X \geq \frac{t}{2} \right] \leq \Pr \left[X \geq (1 + \epsilon) \mathbb{E}[X] \right] \leq e^{-\frac{\epsilon^2 \left(\frac{1}{2} - \epsilon \right) t}{3}} \leq \frac{\delta}{2}$$

- Same for \mathbf{S}_U + union bound \Rightarrow error probability $\leq \delta$

Data Streams

- Stream: m elements from universe $[n] = \{1, 2, \dots, n\}$, e.g.

$$\langle x_1, x_2, \dots, x_m \rangle = \langle 5, 8, 1, 1, 1, 4, 3, 5, \dots, 10 \rangle$$

- f_i = frequency of i in the stream = # of occurrences of value i

$$f = \langle f_1, \dots, f_n \rangle$$

AMS Sampling

- **Problem:** Estimate $\sum_{i \in [n]} g(f_i)$, for an arbitrary function g with $g(0) = 0$.
- **Estimator:** Sample x_J , where J is sampled uniformly at random from $[m]$ and compute:

$$r = |\{j \geq J : x_j = x_J\}|$$

Output: $X = m(g(r) - g(r - 1))$

- **Expectation:**

$$\begin{aligned} \mathbb{E}[X] &= \sum_i \Pr[x_J = i] \mathbb{E}[X | x_J = i] \\ &= \sum_i \frac{f_i}{m} \left(\sum_{r=1}^{f_i} \frac{m(g(r) - g(r - 1))}{f_i} \right) = \sum_i g(f_i) \end{aligned}$$

Frequency Moments

- Define $F_k = \sum_i f_i^k$ for $k \in \{0,1,2, \dots\}$
 - $F_0 = \#$ number of distinct elements
 - $F_1 = \#$ elements
 - $F_2 =$ “Gini index”, “surprise index”

Frequency Moments

- Define $F_k = \sum_i f_i^k$ for $k \in \{0, 1, 2, \dots\}$
- Use AMS estimator with $\mathbf{X} = m(r^k - (r - 1)^k)$
 $\mathbb{E}[\mathbf{X}] = F_k$
- **Exercise:** $0 \leq \mathbf{X} \leq m k f_*^{k-1}$, where $f_* = \max_i f_i$
- Repeat t times and take average $\hat{\mathbf{X}}$. By Chernoff:
$$\Pr[|\hat{\mathbf{X}} - F_k| \geq \epsilon F_k] \leq 2 \exp\left(-\frac{t F_k \epsilon^2}{3 m k f_*^{k-1}}\right)$$
- Taking $t = \frac{3 m k f_*^{k-1} \log \frac{1}{\delta}}{\epsilon^2 F_k}$ gives $\Pr[|\hat{\mathbf{X}} - F_k| \geq \epsilon F_k] \leq \delta$

Frequency Moments

- Lemma:

$$\frac{mf_*^{k-1}}{F_k} \leq n^{1-1/k}$$

- Result:

$$t = \frac{3mkf_*^{k-1} \log \frac{1}{\delta}}{\epsilon^2 F_k} = O\left(\frac{kn^{1-\frac{1}{k}} \log \frac{1}{\delta}}{\epsilon^2} (\log n + \log m)\right)$$

memory suffices for (ϵ, δ) -approximation of F_k

- Question: What if we don't know m ?
- Then we can use probabilistic guessing (similar to Morris's algorithm), replacing $\log n$ with $\log nm$.

Frequency Moments

- Lemma:

$$\frac{mf_*^{k-1}}{F_k} \leq n^{1-1/k}$$

- **Exercise:** $F_k \geq n \left(\frac{m}{n}\right)^k$ (Hint: worst-case when $f_1 = \dots = f_n = \frac{m}{n}$. Use convexity of $g(x) = x^k$).
- Case 1: $f_*^k \leq n \left(\frac{m}{n}\right)^k$

$$\frac{mf_*^{k-1}}{F_k} \leq \frac{mn^{1-\frac{1}{k}} \left(\frac{m}{n}\right)^{k-1}}{n \left(\frac{m}{n}\right)^k} = n^{1-\frac{1}{k}}$$

Frequency Moments

- Lemma:

$$\frac{mf_*^{k-1}}{F_k} \leq n^{1-1/k}$$

- Case 2: $f_*^k \geq n \left(\frac{m}{n}\right)^k$

$$\frac{mf_*^{k-1}}{F_k} \leq \frac{mf_*^{k-1}}{f_*^k} \leq \frac{m}{f_*} \leq \frac{m}{n^{\frac{1}{k}} \left(\frac{m}{n}\right)} = n^{1-\frac{1}{k}}$$

Hash Functions

- **Definition:** A family H of functions from $A \rightarrow B$ is k -wise independent if for any distinct $x_1, \dots, x_k \in A$ and $i_1, \dots, i_k \in B$:

$$\Pr_{h \in_R H} [h(x_1) = i_1, h(x_2) = i_2, \dots, h(x_k) = i_k] = \frac{1}{|B|^k}$$

- **Example:** If $A \subseteq \{0, \dots, p-1\}$, $B = \{0, \dots, p-1\}$ for prime p

$$H = \left\{ h(x) = \sum_{i=0}^{k-1} a_i x^i \bmod p : 0 \leq a_0, a_1, \dots, a_{k-1} \leq p-1 \right\}$$

is a k -wise independent family of hash functions.

Linear Sketches

- Sketching algorithm: picks a random matrix $Z \in R^{k \times n}$, where $k \ll n$ and computes Zf .
- Can be incrementally updated:
 - We have a sketch Zf
 - When i arrives, new frequencies are $f' = f + e_i$
 - Updating the sketch:
$$Zf' = Z(f + e_i) = Zf + Ze_i = Zf + (\text{i-th column of } Z)$$
- Need to choose random matrices carefully

$$F_2$$

- **Problem:** (ϵ, δ) -approximation for $F_2 = \sum_i f_i^2$
- **Algorithm:**
 - Let $Z \in \{-1, 1\}^{k \times n}$, where entries of each row are 4-wise independent and rows are independent
 - Don't store the matrix: k 4-wise independent hash functions σ
 - Compute Zf , average squared entries “appropriately”
- **Analysis:**
 - Let s be any entry of Zf .
 - Lemma: $\mathbb{E}[s^2] = F_2$
 - Lemma: $\text{Var}[s^2] \leq 2F_2^2$

F_2 : Expectation

- Let σ be a row of Z with entries $\sigma_i \in_R \{-1, 1\}$.

$$\begin{aligned}\mathbb{E}[s^2] &= \mathbb{E} \left[\left(\sum_{i=1}^n \sigma_i f_i \right)^2 \right] \\ &= \mathbb{E} \left(\sum_{i=1}^n \sigma_i^2 f_i^2 + \sum_{i \neq j} \mathbb{E}[\sigma_i \sigma_j f_i f_j] \right) \\ &= \mathbb{E} \left(\sum_{i=1}^n f_i^2 + \sum_{i \neq j} \mathbb{E}[\sigma_i \sigma_j] f_i f_j \right) \\ &= F_2 + \sum_{i \neq j} \mathbb{E}[\sigma_i] \mathbb{E}[\sigma_j] f_i f_j = F_2\end{aligned}$$

- We used 2-wise independence for $\mathbb{E}[\sigma_i \sigma_j] = \mathbb{E}[\sigma_i] \mathbb{E}[\sigma_j]$.

F_2 : Variance

$$\begin{aligned}\mathbb{E}[(X^2 - \mathbb{E}X^2)^2] &= \mathbb{E}\left(\sum_{i \neq j} \sigma_i \sigma_j f_i f_j\right)^2 \\&= \mathbb{E}\left(2 \sum_{i \neq j} \sigma_i^2 \sigma_j^2 f_i^2 f_j^2 + 4 \sum_{i \neq j \neq k} \sigma_i^2 \sigma_j \sigma_k f_i^2 f_j f_k\right. \\&\quad \left.+ 24 \sum_{i < j < k < l} \sigma_i \sigma_j \sigma_k \sigma_l f_i f_j f_k f_l\right) \\&= 2 \sum_{i \neq j} f_i^2 f_j^2 + 4 \sum_{i \neq j \neq k} \mathbb{E}[\sigma_j \sigma_k] f_i^2 f_j f_k \\&\quad + 24 \sum_{i < j < k < l} \mathbb{E}[\sigma_i \sigma_j \sigma_k \sigma_l] f_i f_j f_k f_l \leq 2 F_2^2\end{aligned}$$

- $\mathbb{E}[\sigma_i \sigma_j \sigma_k \sigma_l] = \mathbb{E}[\sigma_i] \mathbb{E}[\sigma_j] \mathbb{E}[\sigma_k] \mathbb{E}[\sigma_l] = 0$ by 4-wise independence

F_0 : Distinct Elements

- **Problem:** (ϵ, δ) -approximation for $F_0 = \sum_i f_i^0$
- **Simplified:** For fixed $T > 0$, with prob. $1 - \delta$ distinguish:

$$F_0 > (1 + \epsilon)T \text{ vs. } F_0 < (1 - \epsilon)T$$

- Original problem reduces by trying $O\left(\frac{\log n}{\epsilon}\right)$ values of T :

$$T = 1, (1 + \epsilon), (1 + \epsilon)^2, \dots, n$$

F_0 : Distinct Elements

- **Simplified:** For fixed $T > 0$, with prob. $1 - \delta$ distinguish:

$$F_0 > (1 + \epsilon)T \text{ vs. } F_0 < (1 - \epsilon)T$$

- **Algorithm:**
 - Choose random sets $S_1, \dots, S_k \subseteq [n]$ where $\Pr[i \in S_j] = \frac{1}{T}$
 - Compute $s_j = \sum_{i \in S_j} f_i$
 - If at least k/e of the values s_j are zero, output $F_0 < (1 - \epsilon)T$

$$F_0 > (1 + \epsilon)T \text{ vs. } F_0 < (1 - \epsilon)T$$

- **Algorithm:**

- Choose random sets $S_1, \dots, S_k \subseteq [n]$ where $\Pr[i \in S_j] = \frac{1}{T}$
- Compute $s_j = \sum_{i \in S_j} f_i$
- If at least k/e of the values s_j are zero, output $F_0 < (1 - \epsilon)T$

- **Analysis:**

- If $F_0 > (1 + \epsilon)T$, then $\Pr[s_j = 0] < \frac{1}{e} - \frac{\epsilon}{3}$
- If $F_0 < (1 - \epsilon)T$, then $\Pr[s_j = 0] > \frac{1}{e} + \frac{\epsilon}{3}$
- Chernoff: $k = O\left(\frac{1}{\epsilon^2} \log \frac{1}{\delta}\right)$ gives correctness w.p. $1 - \delta$

$$F_0 > (1 + \epsilon)T \text{ vs. } F_0 < (1 - \epsilon)T$$

- Analysis:

- If $F_0 > (1 + \epsilon)T$, then $\Pr[s_j = 0] < \frac{1}{e} - \frac{\epsilon}{3}$
- If $F_0 < (1 - \epsilon)T$, then $\Pr[s_j = 0] > \frac{1}{e} + \frac{\epsilon}{3}$

- If T is large and ϵ is small then:

$$\Pr[s_j = 0] = \left(1 - \frac{1}{T}\right)^{F_0} \approx e^{-\frac{F_0}{T}}$$

- If $F_0 > (1 + \epsilon)T$:

$$e^{-\frac{F_0}{T}} \leq e^{-(1+\epsilon)} \leq \frac{1}{e} - \frac{\epsilon}{3}$$

- If $F_0 < (1 - \epsilon)T$:

$$e^{-\frac{F_0}{T}} \geq e^{-(1-\epsilon)} \geq \frac{1}{e} + \frac{\epsilon}{3}$$

Count-Min Sketch

- <https://sites.google.com/site/countminsketch/>
- Stream: m elements from universe $[n] = \{1, 2, \dots, n\}$, e.g.
 $\langle x_1, x_2, \dots, x_m \rangle = \langle 5, 8, 1, 1, 1, 4, 3, 5, \dots, 10 \rangle$
- f_i = frequency of i in the stream = # of occurrences of value i , $f = \langle f_1, \dots, f_n \rangle$
- Problems:
 - Point Query: For $i \in [n]$ estimate f_i
 - Range Query: For $i, j \in [n]$ estimate $f_i + \dots + f_j$
 - Quantile Query: For $\phi \in [0,1]$ find j with $f_1 + \dots + f_j \approx \phi m$
 - Heavy Hitters: For $\phi \in [0,1]$ find all i with $f_i \geq \phi m$

Count-Min Sketch: Construction

- Let $H_1, \dots, H_d: [n] \rightarrow [w]$ be 2-wise independent hash functions
- We maintain $d \cdot w$ counters with values:
 $c_{i,j} = \# \text{ elements } e \text{ in the stream with } H_i(e) = j$
- For every x the value $c_{i,H_i(x)} \geq f_x$ and so:
$$f_x \leq \tilde{f}_x = \min(c_{1,H_1(x)}, \dots, c_{d,H_d(x)})$$
- If $w = \frac{2}{\epsilon}$ and $d = \log_2 \frac{1}{\delta}$ then:
$$\Pr[f_x \leq \tilde{f}_x \leq f_x + \epsilon m] \geq 1 - \delta.$$

Count-Min Sketch: Analysis

- Define random variables $\mathbf{Z}_1 \dots, \mathbf{Z}_k$ such that $c_{i,H_i(x)} = f_x + \mathbf{Z}_i$

$$\mathbf{Z}_i = \sum_{y \neq x, H_i(y) = H_i(x)} f_y$$

- Define $\mathbf{X}_{i,y} = 1$ if $H_i(y) = H_i(x)$ and 0 otherwise:

$$\mathbf{Z}_i = \sum_{y \neq x} f_y \mathbf{X}_{i,y}$$

- By 2-wise independence:

$$\mathbb{E}[\mathbf{Z}_i] = \sum_{y \neq x} f_y \mathbb{E}[\mathbf{X}_{i,y}] = \sum_{y \neq x} f_y \Pr[H_i(y) = H_i(x)] \leq \frac{m}{w}$$

- By Markov inequality,

$$\Pr[\mathbf{Z}_i \geq \epsilon m] \leq \frac{1}{w \epsilon} = \frac{1}{2}$$

Count-Min Sketch: Analysis

- All Z_i are independent

$$\Pr[Z_i \geq \epsilon m \text{ for all } 1 \leq i \leq d] \leq \left(\frac{1}{2}\right)^d = \delta$$

- With prob. $1 - \delta$ there exists j such that $Z_j \leq \epsilon m$

$$\begin{aligned}\tilde{f}_x &= \min(c_{1,H_1(x)}, \dots, c_{d,H_d(x)}) = \\ &= \min(f_x + Z_1, \dots, f_x + Z_d) \leq f_x + \epsilon m\end{aligned}$$

- CountMin estimates values f_x up to $\pm \epsilon m$ with total memory $O\left(\frac{\log m \log \frac{1}{\delta}}{\epsilon^2}\right)$,

Dyadic Intervals

- Define $\log n$ partitions of $[n]$:

$$I_0 = \{1, 2, 3, \dots, n\}$$

$$I_1 = \{\{1, 2\}, \{3, 4\}, \dots, \{n-1, n\}\}$$

$$I_2 = \{\{1, 2, 3, 4\}, \{5, 6, 7, 8\}, \dots, \{n-3, n-2, n-1, n\}\}$$

...

$$I_{\log n} = \{\{1, 2, 3, \dots, n\}\}$$

- **Exercise:** Any interval (i, j) can be written as a disjoint union of at most $2 \log n$ such intervals.
- **Example:** For $n = 256$: $[48, 107] = [48, 48] \cup [49, 64] \cup [65, 96] \cup [97, 104] \cup [105, 106] \cup [107, 107]$

Count-Min: Range Queries and Quantiles

- **Range Query:** For $i, j \in [n]$ estimate $f_i + \cdots f_j$
- **Approximate median:** Find j such that:

$$f_1 + \cdots + f_j \geq \frac{m}{2} + \epsilon m \text{ and}$$

$$f_1 + \cdots + f_{j-1} \leq \frac{m}{2} - \epsilon m$$

Count-Min: Range Queries and Quantiles

- **Algorithm:** Construct $\log n$ Count-Min sketches, one for each I_i such that for any $I \in I_i$ we have an estimate \tilde{f}_I for f_I such that:

$$\Pr[f_I \leq \tilde{f}_I \leq f_I + \epsilon m] \geq 1 - \delta$$

- To estimate $[i, j]$, let $I_1 \dots, I_k$ be decomposition:

$$\widetilde{f_{[i,j]}} = \widetilde{f_{I_1}} + \dots + \widetilde{f_{I_k}}$$

- Hence,

$$\Pr[f_{[i,j]} \leq \widetilde{f_{[i,j]}} \leq 2 \epsilon m \log n] \geq 1 - 2\delta \log n$$

Count-Min: Heavy Hitters

- **Heavy Hitters:** For $\phi \in [0,1]$ find all i with $f_i \geq \phi m$ but no elements with $f_i \leq (\phi - \epsilon)m$
- **Algorithm:**
 - Consider binary tree whose leaves are $[n]$ and associate internal nodes with intervals corresponding to descendant leaves
 - Compute Count-Min sketches for each I_i
 - Level-by-level from root, mark children I of marked nodes if $\tilde{f}_I \geq \phi m$
 - Return all marked leaves
- Finds heavy-hitters in $O(\phi^{-1} \log n)$ steps
